How To Create A Python HTTP Server For Web Development?

In this tutorial, we are going to create a Python HTTP server for Web Development. With the help of Python, you can easily create your server with a simple command, and there is no need to install or use any framework for this. So, without any further ado, let's see how it is done:

- First of all, create a folder where our index.html, CSS, and js files will be present.
- Now open the PowerShell window in the same directory by pressing right click and shift button together. Choose the **Open PowerShell window here**.
- Now type the below command and hit enter to create a server:

```
python -m http.server
```

- Now open the browser and head over to **localhost:8000.**
- Boom! You will see that your server has started, and the files of the directory where you've created your server are being served to you.

So, that's how you can create your own server within a few minutes with the help of Python. That's all for this tutorial, and I will see you in the next tutorial. Till then, keep coding and keep learning!
